Modern Water owns, installs and operates world-leading membrane technologies and we are the world-leader in Forward Osmosis (FO) technology. We have successfully implemented and operated our patented desalination process internationally and produce fresh water in some of the most demanding seawater conditions in the world.

Our FO process consistently delivers significant reductions in operational costs, reduced lifetime costs and it reliably produces high quality product water, even in the most challenging conditions.

We use our world-leading FO technology platform in a number of membrane process applications other than for seawater or brackish water desalination. These include: evaporative cooling systems, secondary oil recovery and the development of renewable energy using hydro osmotic power (HOP).

**FO desalination benefits**

- A proven, reliable and robust membrane process
- Energy consumption typically up to 30% lower than conventional Reverse Osmosis (RO)
- Inherently low fouling characteristics (both particulate and biological fouling)
- Significantly reduced product boron levels without post-treatment when compared to conventional RO
- Higher availability than a conventional RO plant due to low fouling, simple cleaning and ease of operation
Forward Osmosis (FO)

- Innovative process solution now fully operational & commercially available (Al Khaluf, Oman - the world’s first commercial FO plant began operation in 2010).
- Competitive advantages over RO.
- Significant further process improvements to come.

Reverse Osmosis (RO)

- Mature, well established technology (Coalinga, California - the world’s first commercial RO plant began operation in 1965).
- Little further improvement likely.

**Technology Status**

Forward Osmosis (FO)

- Extremely low inherent fouling - low pressure, diffusion driven process.
- Possibility to consider reduced pre-treatment.
- FO Membranes are chlorine tolerant allowing effective treatment for bio-fouling.

Reverse Osmosis (RO)

- High pressure - prone to fouling, hydraulic forces increase fouling - a key issue.
- RO Membranes are not chlorine tolerant.

**Membrane Fouling**

Forward Osmosis (FO)

- Typically up to 30% less than RO.
- The more difficult the feedwater the higher the energy saving.

Reverse Osmosis (RO)

- Typically up to 10% more than FO.
- Any degree of fouling, higher than FO.

**Energy Consumption**

Forward Osmosis (FO)

- 42% reduction in energy consumption vs RO at Al Khaluf.

Reverse Osmosis (RO)

- 47% Conversion 65 barg vs 8 barg.

**Operational Costs**

- Less than RO due to higher availability, less chemical cleaning and fewer membrane replacements.
- Extended membrane life - FO membrane life typically twice that of the equivalent RO membrane.

**Boron Removal**

Forward Osmosis (FO)

- Inherently high removal, without the need for post treatment (less than 1 ppm).

Reverse Osmosis (RO)

- Very similar to RO but with less frequent cleaning and increased membrane life.

**Ease of Operation**

Forward Osmosis (FO)

- Poor removal and may require additional costly post treatment system.

Reverse Osmosis (RO)

- Similar to FO but more frequent cleaning and reduced membrane life.

**Capital Cost**

Forward Osmosis (FO)

- Similar capital cost on a like-for-like basis.

Reverse Osmosis (RO)

- Similar capital cost on a like-for-like basis.

**Process explained**

At the heart of the Modern Water process is a recirculating “osmotic agent” system that transfers pure water from the feedwater (eg seawater) to the regeneration (permeate extraction) system.

By linking two highly optimised systems, the FO system and the regeneration system, significant benefits are achieved.

In the first stage, feedwater is fed under low pressure to the forward osmosis membranes, which are highly resistant to fouling and are resistant to oxidising agents. The osmotic agent, on the other side of the membrane, draws fresh water from the seawater due to a difference in osmotic pressure. This fresh water dilutes the osmotic agent.

In the second stage, permeate is extracted from the system. The pure water is removed from the dilute osmotic agent which is regenerated (or concentrated) for reuse in the first stage. This can be achieved in a number of ways depending on the proprietary osmotic agent selected.
